Your operating system has some useful networking tools that come in the form of command line utilities. Here are two main ones that you should read about. 1. Ping: The ping team sends a package of test data from your computer to another network device. Its results tell you whether setting the connection between the computer and the recipient one has been successful and how long it took. Ping is often used to fix network-related problems. 2. Ipnconfig: This command gives you a quick way to identify your IP address. Just type the ipnconfig into the command hint and hit Enter. You'll find an overview of the current network configuration, complete with IP address, subnet mask and default gateway. Ipnconfig paired with some specific parameters can be used to perform other actions. For example, you can use ipnconfig/flushdns to remove the contents of the DNS solution cache. This step is useful when you've changed the values of DNS and want your computer to bring addresses from updated servers. Ping and Ipnconfig are convenient terminal commands, but these are not the only ways to gather information or diagnose network connections. They have GUI equivalents in both desktop and web applications. Terminal utilities like these work on Windows, Linux and OS X. The catch is that sometimes they need a little tweak in syntax or execution depending on the operating system. For example, on OS X, the ping team will continue to ping the net until you click Ctrl-C to interrupt the process. Another example is that ipnconfig is ifconfig on Linux. Have you used a team query to solve network problems or get network information? Or do you prefer to stick to GUI-based utilities instead? Tell us in the comments! How do I track my cell phone location using only my lost phone number? Trying to find or look after the baby? This app can help. About author Akshat Shanbhag (415 Articles Published) More from Akshat Shanbhag Did you know that every applet control panel in Windows can be opened by executing a specific command? It's true! You just have to know what kind of team it is. Sometimes it's easier, and maybe even in some cases, to open the applet in the control panel from the command line to Windows. For example, if you're building a script or software that should open applet, these little tricks help. Lifewire/Kyle Fewel More common, however, is a situation where your computer is misbehaving in a certain way that prevents you from moving as usual without leaving you with no way to open the control panel normally, which you probably need to do to solve this problem! Disappointing, we know. Often, however, such situations still allow the team to be discharged. That's where it's very convenient to list management team tricks are shown in the giant table below. Start by opening Command Prompt, or even just Run boxes (WIN-R). Once Once perform, just as shown below, a command that matches the applet control panel you want to open. It's that simple. Maybe you don't want to open a specific applet control panel from the Prompt command, or run a box, but instead you want the control panel yourself to open... the control panel is a homepage, so to speak. It's as simple as running a command line in any version of Windows. Don't add anything after it - just control by itself. The control panel will open just as it does when you do all the clicking or clicking you normally do to open it normally. Control lrprops.cpl XP Color is not available by default, but is available for free from Microsoft. You can take a copy from MajorGeeks. WinColor.exe is to be launched from the C folder: Program Files Pro Imaging Powertoys-Microsoft Color Control Panel Applet for the Windows XP folder. I listed the device manager here because it's such a widely used Windows feature, but please know that this is not the true apple control panel in Windows XP. Learn how to open a Windows XP device manager for more information. Applet mail is only available if the Microsoft Office Outlook version is installed. The mlcfg32.cpl management team should be launched from the C folder: Microsoft Office OfficeXX, replacing it with a replacement with a folder that is attached to the Microsoft Office version. The ODBC Data Source administrator was removed from the control panel after Windows XP, but is still available from administrative tools. In Windows 8, 7, and Vista, task planning is performed by Task Scheduler, which is not available directly from the control panel. However, this command in these versions of Windows will be re-run for scheduler. Software Explorers is the name of the applet control panel for Windows Defender, available for free here as part of Microsoft Security Essentials. Msascui.exe must be launched from the C folder: Program Files and Windows Defender. The sapi.cpl management team must be run from the C folder: Program Files (General Files) and Microsoft Shared.Speech. Windows Defender is available in Windows XP, but the applet control panel is instead called Software Explorers. The Windows Update is also used in Windows XP, but only through the Windows Update website, not through the applet control panel, as in later versions of Windows. In Windows 8, bthprops.cpl opens devices in PC settings that list any Bluetooth devices. In Windows 7, bthprops.cpl opens a list of Bluetooth devices under devices and printers. In Windows Vista, bthprops.cpl opens a true applet control panel called Bluetooth devices.
